Stat 5309 Midterm Project

Tom Wilson Mar 21, 2019

1

The effective life of insulating luids at an accelerated load of 35 kV is being studied. Test fluid_data have been obtained for four types of fluids. The results were as follows:

\mathbf{a}

Either read fluid_data into R or create the fluid_dataframe.

lifetime
17.6
18.9
16.3
17.4
20.1
21.6
16.9
15.3
18.6
17.1
19.5
20.3
21.4
23.6
19.4
18.5
20.5
22.3
19.3
21.1
16.9
17.5
18.3
19.8

Build a linear model, using aov. Is there a significant difference among treatment means? which fluid gives the longer life?

Given that there is no difference in lifetime between fluid types, we would expect a result at least this extreme 5.25% of the time. At a confidence level of 95% we fail to reject the null hypothesis and conclude that any difference observed is due to chance.

 \mathbf{c}

Construct a 95% Confidence Interval for themean life of fluid 2.

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

```

```

The difference between type 4 and type 1 is between -0.7213 and 6.7213 with 99% confidence.

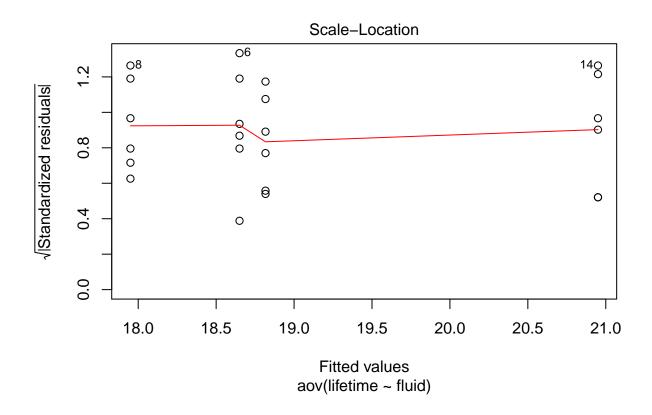

\mathbf{d}

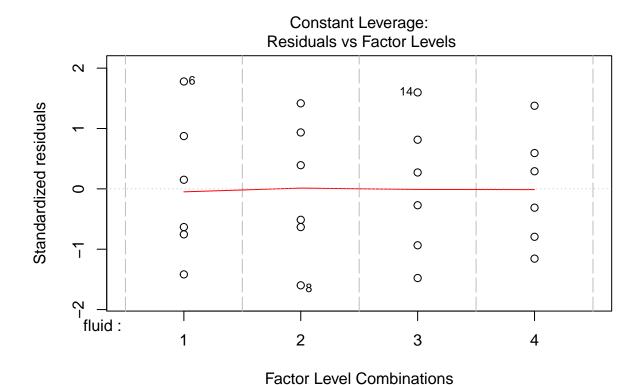

Perform a complete 3-part residuals check.

```
plot(insulation_life_model)
```

Independence

Based on a plot of standardized residual vs factor level (in this case, fluid type) the residuals are independent of fluid type.

Normality

Based on a quantile-quantile plot te residuals are very close to normally distributed with a mean of zero.

homoscedasticity

based on a plot of residual vs fitted values, variation in residual is constant.

 \mathbf{e}

Calculate the number of replicates for a power of 0.99

```
##
##
        Balanced one-way analysis of variance power calculation
##
##
            groups = 4
##
                 n = 16.45871
##
       between.var = 1.675833
##
        within.var = 3.299667
         sig.level = 0.05
##
##
             power = 0.99
##
## NOTE: n is number in each group
```

$\mathbf{2}$

\mathbf{a}

Either read data into R or create the dataframe.

17 replicates are needed to achieve a power of 0.99.

```
oils <- c("1","2","3")
trucks <- c("1","2","3","4","5")
fuel_data <- expand.grid(truck=trucks,oil=oils)</pre>

Build a linear model. Is there any significant difference of means about the oil types? Which oil type gies the lowest fuel consumption?

```
fuel_consumption_model <- aov(formula = fuel_data$fuel_consumption ~ oil+truck,data=fuel_data)
summary(fuel_consumption_model)</pre>
```

 \mathbf{c}

Is the blocking approach effective?

d

Do a complete residual assumption check.

3

Suppose that in in Problem 4-15, the engineer suspects that the workplaces used by the four operators may represent an additional source of variation. Analyze the data from this experiment (use $\alpha = 0.05$) and draw conclusions.

\mathbf{a}

Set up a dataframe with 2 blocking factors (order and operator) and treatment (A,B,C,D)

```
workplace_data %>% kable()
```

operator	$order_of_assembly$	workplace	observation
op1	1st	С	11
op2	1st	В	10
op3	1st	D	14
op4	1st	A	8
op1	2nd	В	8
op2	2nd	\mathbf{C}	12
op3	2nd	A	10
op4	2nd	D	12
op1	3rd	A	9
op2	3rd	D	11
op3	3rd	В	7
op4	3rd	\mathbf{C}	15
op1	$4 ext{th}$	D	9
op2	4th	A	8
op3	$4 ext{th}$	\mathbf{C}	18
op4	4th	В	6

Use Latin Square to analyze the treatment means.

\mathbf{c}

Which level combination brings the lowest time?

4

The factors that influence the breaking strength of a synthetic fiber are being studied. Four production machines and three operators are chosen and a factorial experiment is run using fiber from the same production batch. The results follow.

\mathbf{a}

Either read data into R or create the dataframe.

```
)
fiber_data %>% kable()
```

machine	operator	strength
1	o1	109
2	o1	110

## ---

## Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

 \mathbf{c}

Create a boxplot of

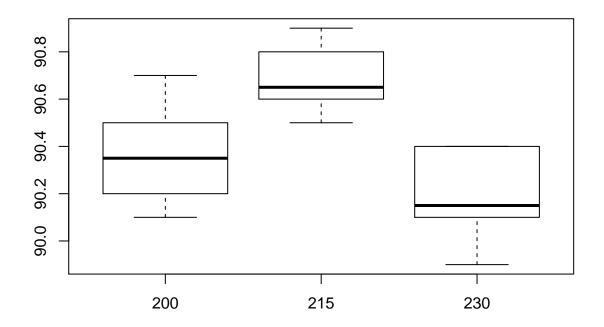

yield vs temp

boxplot(yield~temperature, data=process)

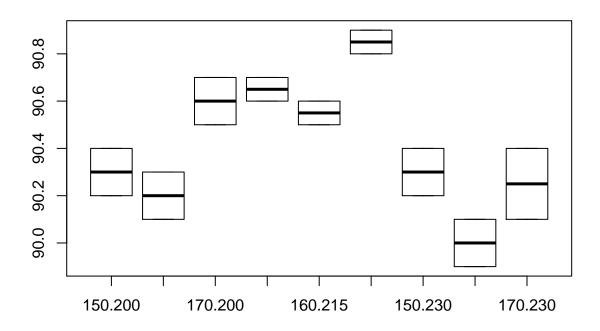

yield vs pressure

boxplot(yield~pressure, data=process)

yield vs temp and pressure

boxplot(yield~temperature*pressure, data=process)

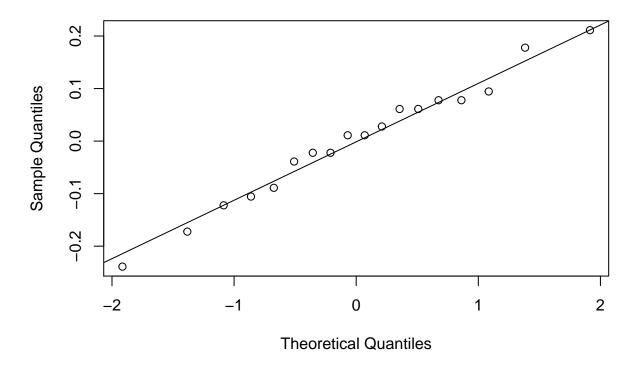

\mathbf{d}

Perform a residuals assumption check

```
qqnorm(yield_model$residuals)
qqline(yield_model$residuals)
```

Normal Q-Q Plot

The residuals are consistent with a normal distribution centered on zero with constant variance.

$\mathbf{2}$

Johnson an dLeone describe an experiment to investigate warping of copper plates. The two factors studied were the temperature and the copper content of the plates. The response variable was a meaure of the amont of warping. The data were as follows.

\mathbf{a}

Set up the dataframe

17,21,22,31))

copperplate %>% kable()

copper_content	temperature	warping
40	50	17
60	50	16
80	50	24
100	50	28
40	50	20

##

##

build a response model surface (RSM) with warpage as response, use rsm().

rsm(formula = response ~ SO(temp_nums, cu_nums), data = copperplate)

Estimate Std. Error t value Pr(>|t|)

```
temp_nums <- copperplate$temperature %>% as.numeric()
cu_nums <- copperplate$copper_content %>% as.numeric()
response <- copperplate$warping
copper_model<- rsm(response ~ SO(temp_nums, cu_nums), data=copperplate)
summary(copper_model)
